

HPV vaccine carries 25% chance of lifelong sterilization, study finds

Aug 24 2018

A new research study has found that 25% of girls who receive the Human Papillomavirus (HPV) vaccine end up sterilized. They will never be able to conceive children.

This information comes from a study published in the Journal of Toxicology and Environmental Health in June 2018. The study is titled, "A lowered probability of pregnancy in females in the USA aged 25–29 who received a human papillomavirus vaccine injection." <https://www.tandfonline.com/doi/abs/10.1080/15287394.2018.1477640?scroll=top&needAccess=true&journalCode=uteh20> to read the study for yourself and download a copy before Big Pharma scrubs it from the internet.

Researchers examined 8 million women in the United States between 25 and 29. Among married women who had never been vaccinated with the HPV vaccine, 75% had had at least one child. Among married women who had been vaccinated, the number was 50%. The same gap existed in unmarried women – about 25% fewer vaccinated women had conceived children. The study's authors report that statistically if all 8 million women in the study had been vaccinated, the United States would have suffered a catastrophic drop in the US birth rate that would have translated into 2 million fewer babies.

The study adds that many vaccine recipients have reported "primary ovarian failure" – girls in their teens and young women in their 20s are suffering late-stage menopause, triggered by the vaccine. Virginia, Texas and the District of Columbia have made the HPV vaccine mandatory for girls once they reach 6th grade, otherwise they can no longer attend public school. Rhode Island jabs girls in 7th grade. California and many other states are considering legislation to make the HPV vaccine mandatory for public school attendance.

If you raise any questions about the vaccine schedule in America at all, the pro-vaccine crowd will begin screeching that you want to kill children. Are we really curing something like polio, which used to leave victims with crippled limbs for life when we vaccinate children against HPV? Not even close!

HPV causes genital warts in some carriers. According to the CDC, most people who contract HPV will never show any symptoms at all. There is no treatment for it, but the virus goes away on its own. Out of every 5,575 women who contract HPV, one will die from complications from a related cancer.

You are more likely to drown, choke to death in a restaurant or be killed in a bicycle accident than to die from an HPV infection. Here's another gut-punch: The vaccine is no guarantee that a person will not contract this mostly-benign virus. It merely reduces the chances.

Is it worth sterilizing 25% of the women in America for that?

HPV can only be transmitted sexually. In other words, HPV is 100% preventable if you practice monogamy. If you don't have sex until you are married, and you don't commit adultery against your spouse, you have a zero percent chance of contracting HPV.

How many girls would opt out of the HPV vaccine if they knew it carried a 25% chance of lifelong sterilization? "This shot will partially protect you against one of the thousands of sexually-transmitted diseases available, BUT... there's a one in four chance you'll never be able to have children if we give you the shot."

The price for the HPV vaccine should be too high for any parent to seriously consider it for their daughters.

Unfortunately for most Americans, almost every state is now considering legislation to make the HPV vaccine mandatory, and Big Pharma is throwing a lot of money around to make that happen. Our duty is to get the results of this research study into as many lawmakers' hands as possible.
